

Component based development

Controlling complexity in a growing app

Supporting Service Technicians

allliander

Project characteristics

- 500 users
- Used 24/7
- 10 team members (8 developers)
- 3 years of development

Tech stack

- Android app based on UI5
- Cloud Foundry on SAP Cloud Platform
- Node.js

Split the app in components

Components...

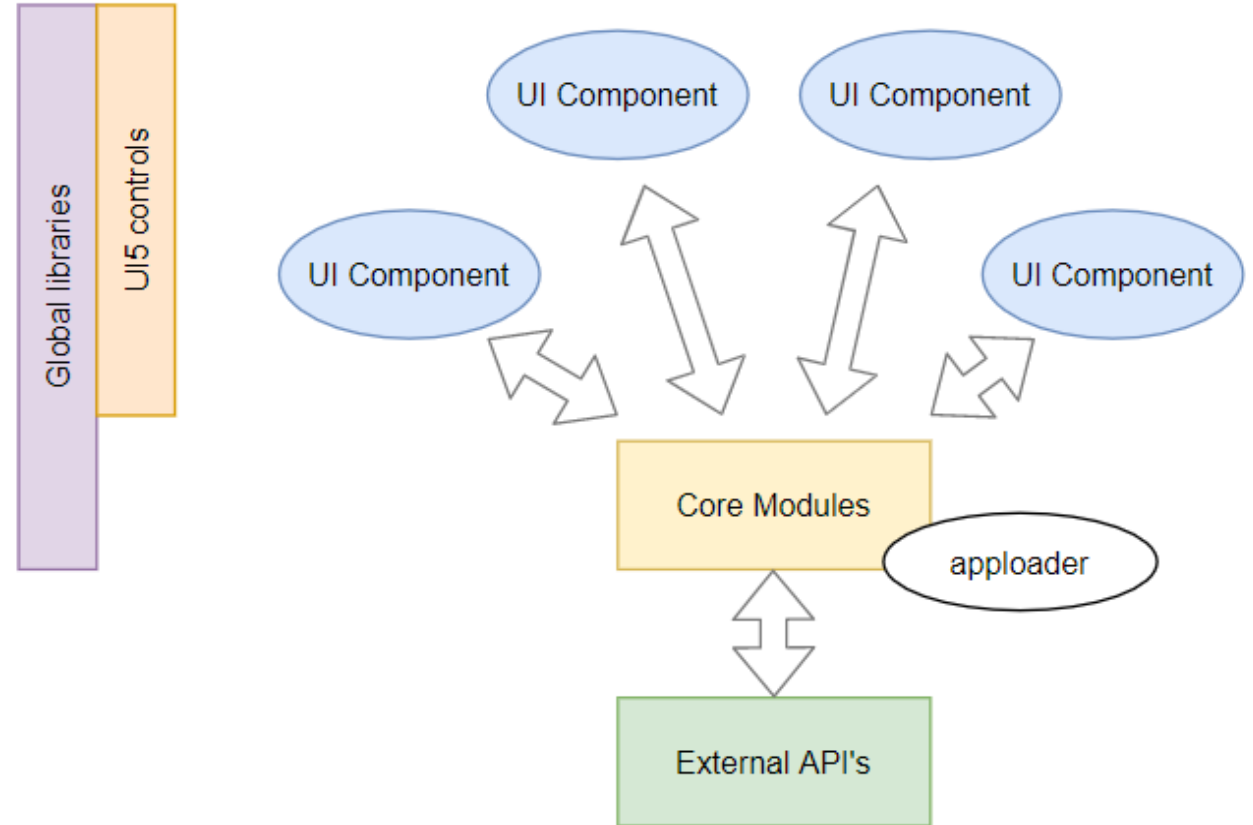

- can be run and tested separately and therefore are easier to develop.
- are easier to reuse in other applications.
- make it easier to work together with a large team

Rules for components

A component...

- covers a well-defined part of the application
- can be run by itself
- doesn't know anything about the other components (!)
- has limited dependencies:
 - a limited set of 'core' modules
 - some ui5 libraries, custom controls and utilities

Core-modules

Core-modules...

- deliver generic functions to the components
- offer an abstraction on external API's

Examples

- Logging module
- Backend API abstraction
- Eventbus

Shell component

The shell component...

- is the starting point for the user
- places components in the screen

It doesn't...

- contain startup logic

Apploader

The apploader...

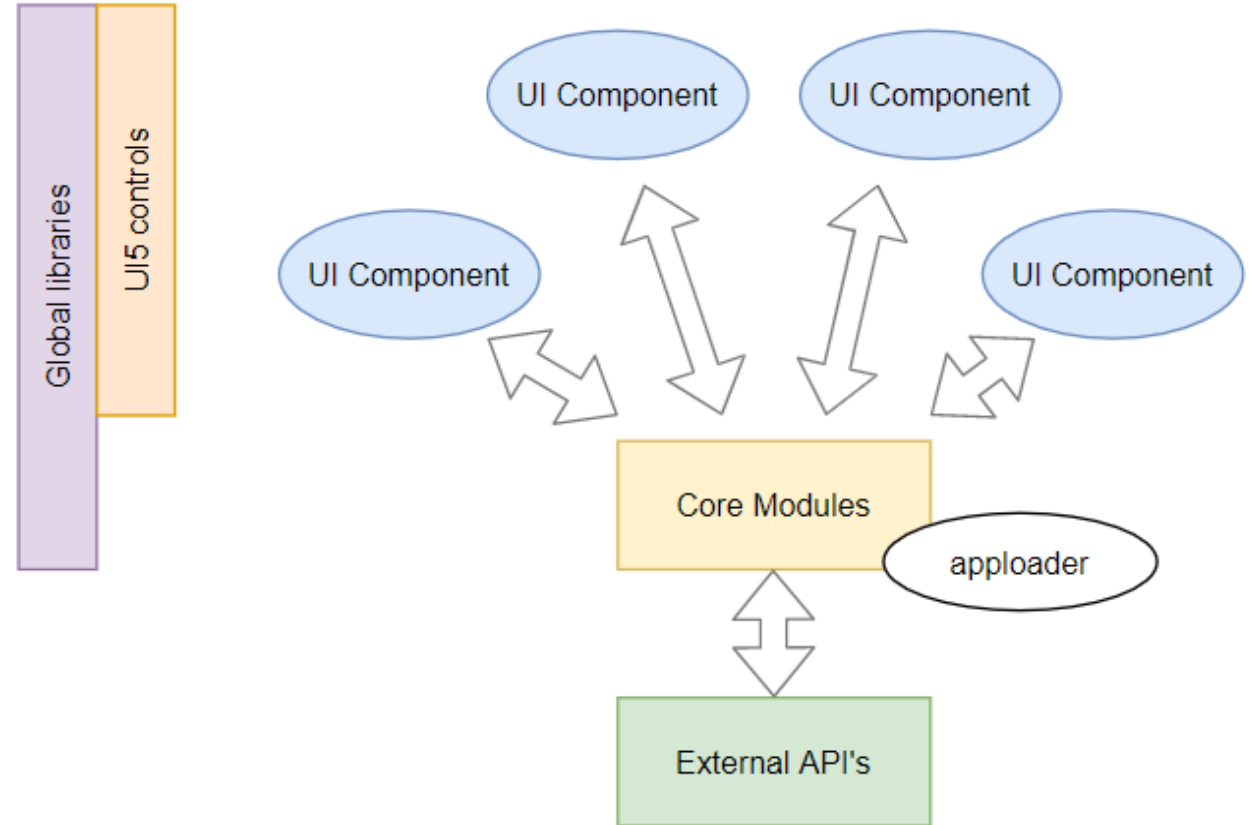

- contains the startup logic for the app
- can start any component
- a started component runs independently

It doesn't...

- contain UI

Example logic

- Show (and hide) a splashscreen
- User authentication and authorization

Advantages

Testing

- Components can be tested separately end-to-end (e.g. uiveri5, opa5)
- Core-modules can be unit-tested separately (e.g. qunit)

Collaboration with others

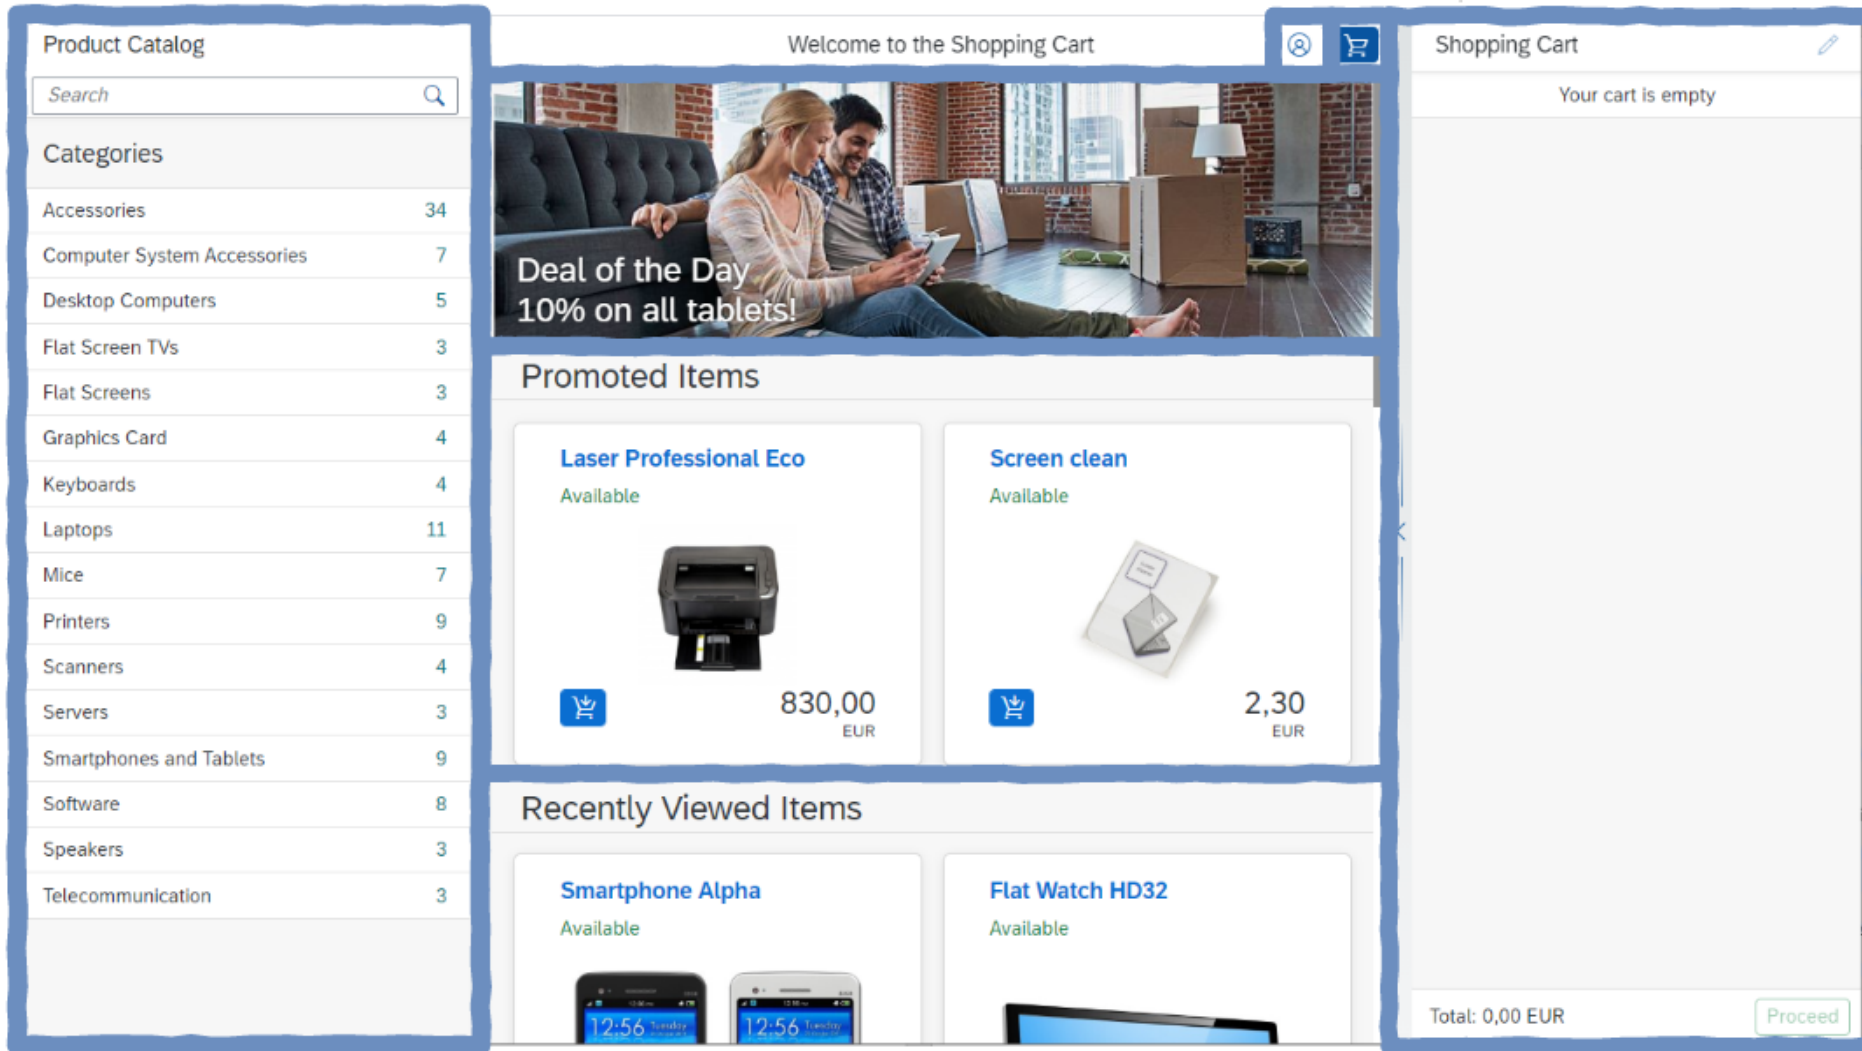

- Separation of concern
- Splitting responsibility

Reusability

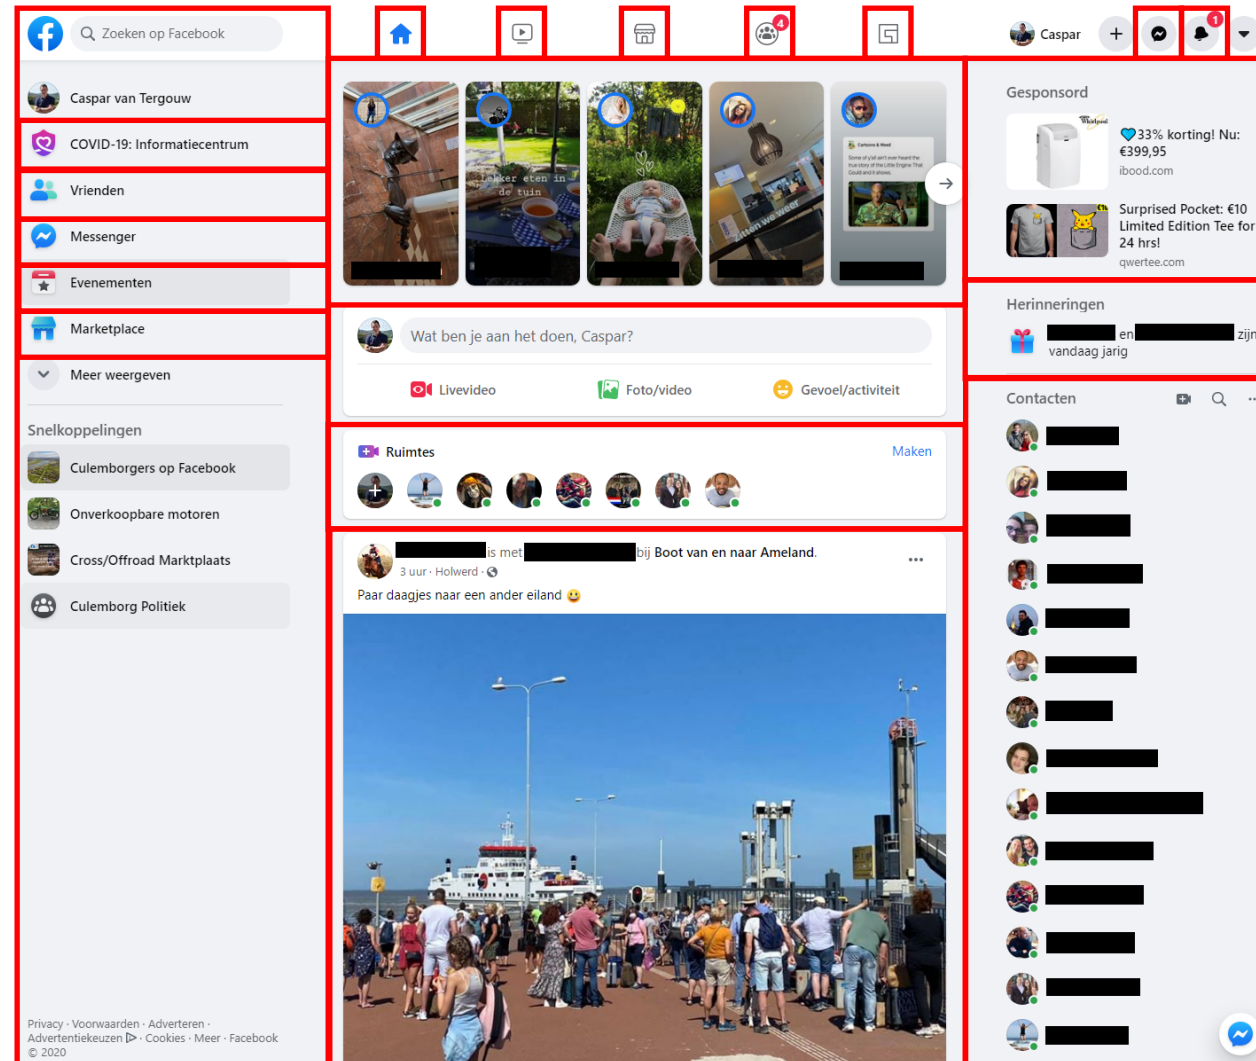

- Abstraction on UIComponent

Migrating to components

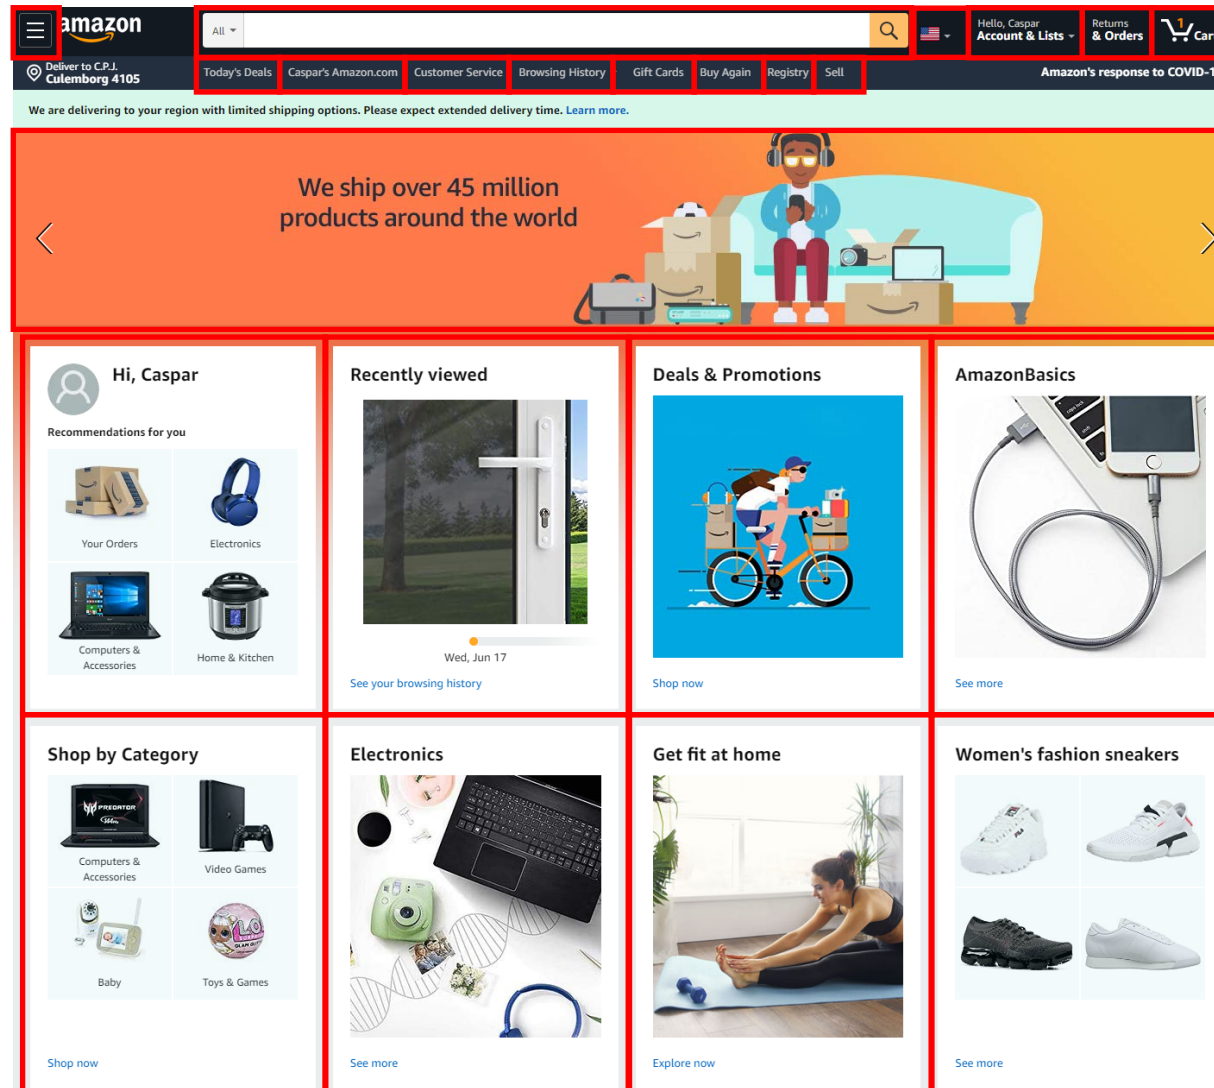

Split the UI

Examples (1 of 2)

Examples (2 of 2)

Thank you.
